ABSTRACT

This paper reports the current state of an ongoing collaborative project which aims to promote modelling and simulation of energy in buildings by making self-learning course material available on the World Wide Web (WWW).

INTRODUCTION

Computer modelling and simulation has become a very important technology for assisting engineers with their non-trivial task of designing/analysing buildings and associated environmental systems such that the result is low energy consumption, good indoor conditions and minimal impact on the environment in general.

This fact is recognised by many engineering schools and in several cases the technology has been fully integrated in the curriculum; see for example (Clarke 1994).

The WWW is emerging as a powerful medium for dispersing and acquiring all kinds of information. For various reasons - such as graphical attractiveness, low accessibility threshold level and flat learning curve - it seems to appeal to students, and therefore it might prove to become an efficient platform for educational purposes. The latter still need to be researched though and is an issue currently receiving increased attention in (higher) education (see for example TALiSMAN 1997).

This paper describes the results of a project which aims to widely introduce building energy modelling and simulation classes by making hypertext courseware available on the WWW.

BACKGROUND

The new democracies in Central and Eastern Europe (CEE) are characterized by an ongoing process of overall transition towards a market economy. This restructuring process involves rapidly changing needs of the labour market. Skills and knowledge in the areas of quality control in engineering and global

environmental manage were not developed under the previous central controlled economy.

In the current context we can see an increasing need for graduates who are fluent in the professional language and who are familiar with technical and economical approaches to these problems in CEE countries.

Furthermore, the global effort for integration of CEE countries into European structures underline the emphasis on compatibility and equivalence with EU universities.

This paper stems from a project which aims to address these needs by restructuring curricula of four higher education institutions in Slovakia and three higher education institutions in Bulgaria by introduction of energy modelling and simulation courses using information technology.

The project (funded as Structural Joint European Projects by the European Union TEMPUS programme, a trans-European cooperation scheme for higher education) attempts to reach two major target groups. Firstly, final year (or MSc) students in building or mechanical engineering, in order to equip these students with required skills and knowledge, before entering the competitive labour market. Secondly, a structure will be created, which enables provision of continuing education for industry (in collaboration with industrial partners).

This three year project (1995 - 1998) comprises three main components: provision of the infra-structure (ie the necessary hardware) for the CEE partners (about 60% of total budget), updating and training of the staff involved (about 20% of total budget), and development, implementation and integration of courseware (about 20% of total budget). The current paper focuses on the courseware component.

COURSEWARE

The goal to create integrated and interdisciplinary classes and the aim to emphasize compatibility and equivalence with EU universities, led to the

conclusion that the classes need an international dimension, and are therefore in the English language.

The courseware is organized as (relatively) compact modular texts with emphasis on graphical representations. The classes are prepared in hypertext (HTML, Hypertext Markup Language) and include Computer Aided Learning features such as in-built exercises, assignments, sample answers, reference material, etc.

The compact and modular structure enables easy integration of interdisciplinary material. Furthermore, the courseware can easily be reorganized in order to suit additional purposes and target groups (i.e. continuing education for industry) or later to incorporate new developments in the field. Effectively, the material can be used in a variety of ways:

- * *in self-learning mode,*
- * *for distance learning,*
- * *as online course material,*
- * *for dissemination purposes,*
- * *as supporting lecture material,*
- * *as reference material in project work,*
- * *to encourage student study and research.*

The courseware constitutes three common "international" classes. The idea is that eventually about 95% of the material will be identical in the partner institutes, and about 5% will be specific to allow for special needs such as national codes, local practices and materials. In this way by the end of the project there will be set of fully EU compatible and equivalent classes.

Currently the courseware consists of three main blocks, **Introduction**, **Practice**, and **Theory**, which - in case of self-learning - are designed to be taken in chronological order:

INTRODUCTION: Why you should use building energy and environmental simulation.

This is a short introductory class which aims to generate interest and motivation for using the technology of computer modelling and simulation of energy in buildings.

Using a range of real case studies, students are given an overview of the main tasks involved in a simulation study:

- * problem analysis and model creation;
- * setting up and performing simulations;
- * analysing results and generating "design knowledge".

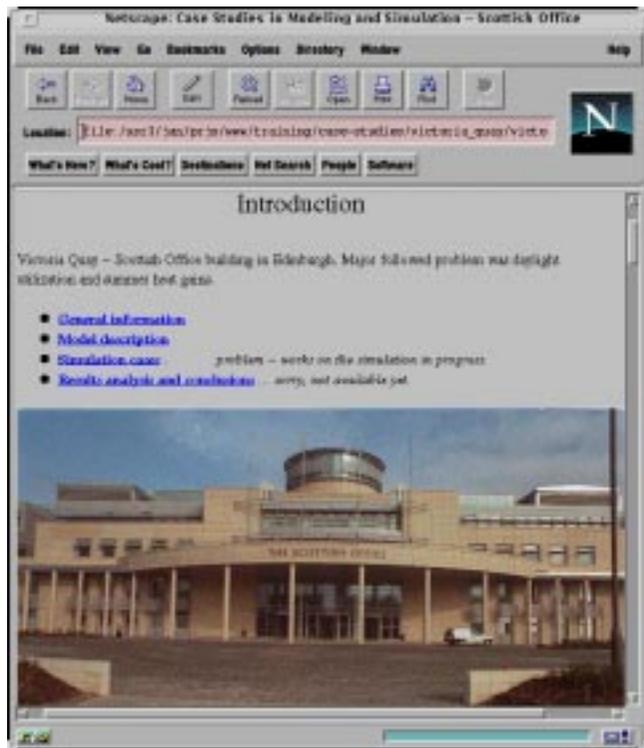

Figure 1 Introduction of case study regarding daylight utilization and summer heat gains in The Scottish Office development

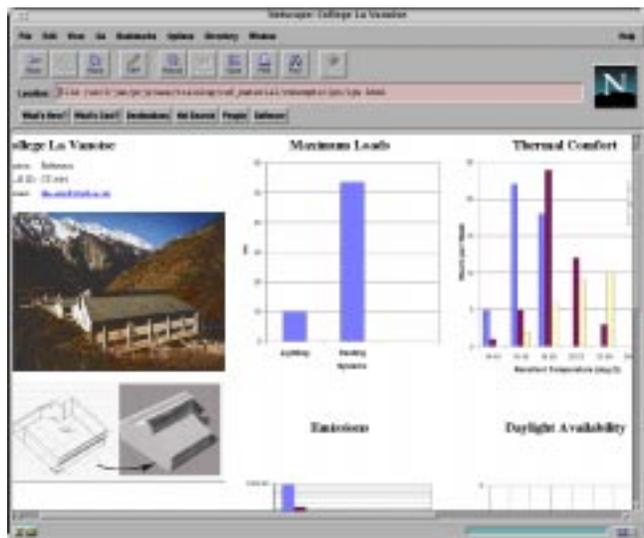

Figure 2 Some results of case study regarding daylight usage in French school

Figure 1 and Figure 2 are taken from two different case studies and illustrate the introduction and some simulation results respectively.

The various case studies aim to illustrate that simulation can be used to predict and assess energy consumption, load distributions, air and fluid flow rates, thermal and visual comfort, daylight

Expert Level Exercises

Advanced topics

- * Making Models: CAD and Attribution
 - * Making Models: Fluid Flow, Plant and Control Networks
 - * Making Models: Enhanced Resolution
 - * Integrated Performance Appraisal
- Practical ESP-r model development
- * Edit/ compile/ link test cycle

In order to be able to use and appreciate ESP-r, it is assumed that the student has access to a Unix workstation and that a copy of the ESP-r software has been installed by the system manager.

For research and educational purposes the University of Strathclyde is normally able to offer a free system license. The restrictions imposed by the license agreement are primarily that it is not allowed to undertake commercial work or pass copies to a third party.

THEORY: Finding out how building energy modelling and actually works.

Some of the students will want to know more and will be interested in how modelling and simulation actually works.

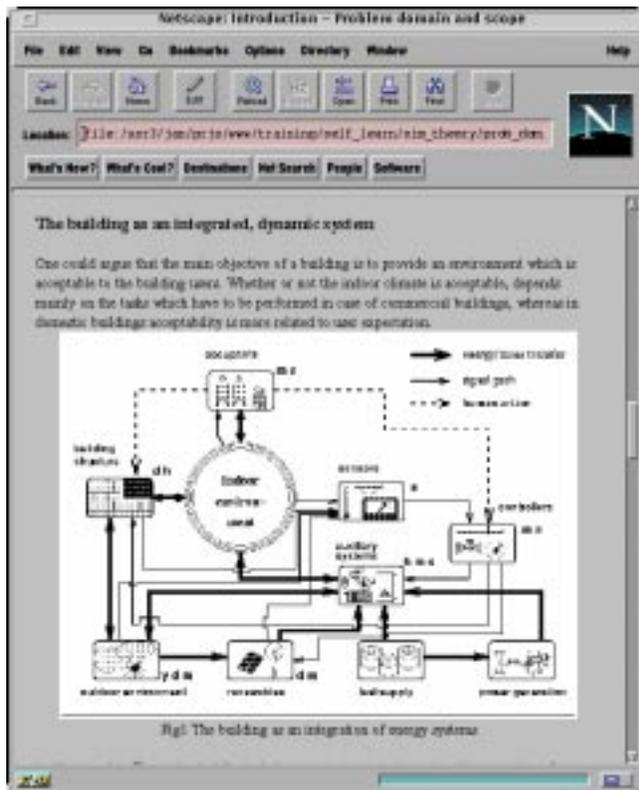

Figure 4 Typical example from theory section showing the building as an integration of energy systems

The material in this module aims to give an understanding of the theoretical and operational principles underlying this new technology. In a series of elements as outlined below, the class introduces the assumptions and limitations which underlie the methods currently used to appraise the energy performance of buildings and their associated environmental control systems. Particular attention is given to methods for representing and integrating building energy and mass transfer processes. The subjects are developed from basic principles assuming limited knowledge of computers and application software. The associated exemplars are designed to demonstrate theoretical concepts introduced in the tutorial material, and to gain practical experience in using this new technology.

The following subjects are addressed:

Part 1: Introduction

- Problem domain and scope
- Energy modelling techniques

Part 2: Modelling Building Energy Processes

- Heat and mass transfer through solids
- Heat and mass transfer by convection
- Heat and light transfer by radiation
- Energy transfer by electricity

Part 3: Modelling Building Energy Systems

- Building structure
- Auxiliary systems
- Control systems
- Occupants
- Outdoor environment
- Integration

Part 4: Simulation for Environmental Engineering

- Quality control
- Methodology
- Case studies

Part 5: Close

- Modelling and simulation context
- Conclusions

In total the class has 17 sub-modules each comprising a list of key concepts, an outline of the lecture structure, a summary, course material for studying by the student, and often links to further reading material.

Each module ends with an assignment (plus some sample answers) which aims to link the theory to practice. As an example, the assignment following the sub-module on quality control reads:

As a member of the design team you are using modelling and simulation to assess the relative

performance of various fenestration options for a new multi-purpose building. The design is still in an early phase, and detailed information is not yet available.

Discuss which error sources (internal or external) are likely to be more dominant in this situation, and suggest a procedure or approach which will reduce the impact of the error sources on your advice to the other team members in terms of which fenestration option will be best.

Both the **Introduction** class and the **Theory** class are very general in terms of modelling and simulation software; they are independent of any programme. For reasons indicated above it is only the **Practice** class which is specific in terms of a software product.

In developing the hypertext material we started from existing material such as existing course notes, papers, articles etc. This material was then transformed into HTML format, cross-links were established (for example from practical and theory sections to case studies) and where possible links to other WWW sites were introduced (for example to a Unix training site and to various building energy related sites).

At numerous locations in the text, students have access to a range of additional information under a variety of topics. For example:

- a **general glossary of terms** related to modelling and simulation for environmental engineering;
- **technical dictionaries** comprising terms commonly used in modelling and simulation of energy in buildings, currently in Bulgarian - English, Czech - English, Dutch - English, Slovak - English, and the inverse forms of these;
- a collection of **hot-links to energy related WWW sites** providing information in the area of energy in buildings;
- various ESP-r specific materials such as an ESP-r glossary of terms; an ESP-r tutorial; and an ESP-r "Frequently Asked Questions" collection.

In this way there exist a number of classes which form study material which is not "restricted" as a normal text book in terms of the material on offer, but which will allow students to find more and more information by digging deeper into the WWW material. Basically the assignments are designed and used to ensure a minimum level of studying.

On completion of the three classes students should appreciate the capabilities and limitations of the various methods for assessing the thermal behaviour

of buildings, including energy efficiency and indoor comfort. They should also:

- appreciate that environments result from complex interactions of many energy and mass transfer mechanisms;
- have a basic knowledge of how to apply computer modelling and simulation to address this complexity;
- understand the theoretical and operational principles of contemporary modelling programs;
- appreciate the limitations of current design support and performance evaluation tools and the issues to be addressed to bring about their improvement;
- possess practical skills in using the technology in an environmental engineering context.

IMPLEMENTATION

As indicated above, initial versions of the courseware has been developed. Currently this constitutes about 12 Mbyte of HTML and image files.

The courseware has been implemented on various WWW servers for efficient access from the partner countries. The preferred WWW location for global access is:

**[http://www.strath.ac.uk/Departments/
/ESRU/courseware/Class-mod+sim/Intro.html](http://www.strath.ac.uk/Departments/ESRU/courseware/Class-mod+sim/Intro.html)**

The information technology aspect of the courses allows self-learning, relatively easy maintenance of the course material, but - most importantly - it provides almost unlimited dissemination possibilities (anyone with Internet access can use the course material). This ensures that the project deliverables will be "automatically" dispersed to other universities and schools within and outwith the countries involved, as well as to practitioners in the construction industry and elsewhere.

As part of the Tempus project the material is currently being introduced in new and existing classes. Due to its modularity the material can be incorporated into the curriculum either as complete classes or in bits and pieces e.g. case studies, parts of theory, etc. The modules can be used for self-study or may be used as additional reading in other classes.

In the University of Strathclyde the courseware has already been fully integrated in two under-graduate classes and in one post-graduate module. The courseware is also used for continuing education purposes.

In order to assure successful implementation, for the other partners target groups with appropriate time schedules were defined, for instance in the case of the Slovak Technical University:

First year:

Post-graduate students were the first target group in order to test the courseware. In Slovakia post-graduate students are members of staff and as such their updating and retraining will have a significant impact during the second and third year of the project. The MSc course in Building Engineering has been restructured and three new classes have been incorporated in the curriculum.

Second year:

A limited group of final year students has been selected as the next target group in order to enable a final check before widely introducing the new classes in the under-graduate curriculum. Two existing final year classes (15 weeks each) on Energy Efficient Building Design and on Special Building Construction have been upgraded by incorporation the courseware in the tutorial part of these existing classes.

Third year:

All final year students of the Building Engineering MSc degree course will have the courseware in the normal curriculum. In this stage, also continuing education courses for industry will be made available to enterprises and practice.

RESULTS

Successful completion of the project will provide the following results:

- CEE participants will have the necessary hardware infra-structure for education (teaching/computer laboratories), software for education, updated and trained staff, training capacities for continuing education to be offered to industry, restructured existing courses, and will have introduced three new classes.
- All participants will have three EU compatible and equivalent courses, international links with other universities, and the courseware as above.

It is too early to report on results in terms of increased/decreased learning efficiency.

Current feed-back from students suggest that they appreciate the medium in which the material is

presented. Early observations and experience suggests that on average students learn quicker and more independent; ie putting less demand on the supervisor/ teacher.

Although some students report 'to get lost', most students are positive, especially regarding the appearance and richness of the material, which actively encourages students to dig deeper at the click of a (mouse) button.

CONCLUSIONS AND FUTURE WORK

The major outcomes of the project can be characterized as follows:

- + developed and implemented new interdisciplinary courses and courseware at three Slovakian, three Bulgarian, and - to a certain extent - two West European universities;
- + enabled infra-structure (teaching/computer IT laboratories) at the participating CEE institutions;
- + retrained and updated staff from CEE institutions;
- + provided platform to further develop continuing education for Slovakian and Bulgarian industry;
- + enhancement of inter-university collaboration in terms of compatible and equivalent course development;
- + unlimited global dissemination potential of the courseware which is being developed within the project.

As indicated above, the project is not at all finished yet, and indeed it is our intention to continue development and improvement of the hypertext courseware once this Tempus project is completed. In a sense, development of this type of courseware is just starting. Many aspects need to be explored further. We therefore invite feed-back and will obviously appreciate any contributions very much.

Future work will certainly involve comparison of this type of hypertext courseware to more traditional course notes and text books in terms of educational efficiency.

Acknowledgements

The authors are deeply indebted to several colleagues in the University of Strathclyde for contributions towards the courseware. The authors would also like to thank all other project partners: Technical University Kosice, University of Agriculture Nitra, and Technical University Zvolen, in the Slovak Republic, and South-West University 'Neofit Rilsky',

Sofia Higher Inst. of Architecture and Civil Engineering, and the Ministry of Regional Development and Construction in Bulgaria. Courseware contributions were also provided by colleagues from the Czech Technical University in Prague.

All participants and collaborators in the EU TEMPUS Structural Joint European Projects S_JEP-09481-95 and S_JEP-09909-95 gratefully acknowledge support of the European Union, as represented by the European Training Foundation in Torino.
